12.5 Image Sources 41
CHAPTER 13: APPENDIX 42

CHAPTER 1

INTRODUCTION

Face recognition has become one of the most widely adopted and researched biometric technologies in recent years. With applications ranging from security surveillance and attendance systems to user authentication in mobile devices, face recognition offers a non-intrusive and contactless method of identity verification. This project presents a **real-time face recognition system with a graphical user interface (GUI)** using **OpenCV, Dlib, and face_recognition** libraries in Python.

The system is designed to recognize, verify, and register faces in real-time through a webcam feed. By comparing input frames with pre-encoded facial features from known images, the application identifies individuals with high accuracy. This solution not only enhances convenience and efficiency but also provides a foundation for various real-world applications like classroom attendance, door access control, and security logging.

This chapter introduces the challenges in existing systems, the advantages offered by the proposed system, and the primary objectives achieved by this project.

1.1 Problem Statement

In today's technology-driven world, facial recognition has emerged as a powerful tool for identification and authentication. However, the deployment of face recognition systems in small-scale or offline environments remains limited due to several challenges. This project addresses the need for a secure, efficient, and offline face recognition solution that is both accessible and affordable.

1. **Inefficiency of Traditional Methods:**
   Manual attendance tracking and identity verification methods are time-consuming and prone to errors or manipulation. These outdated systems are not suitable for real-time applications in educational or office settings.
2. **Dependency on Internet-Based Solutions:**
   Most modern face recognition systems require cloud-based APIs or online services, which raises privacy concerns and makes them unreliable in areas with poor connectivity or strict data regulations.
3. **Lack of Technical Usability:**
   Many existing systems lack user-friendly interfaces, making them difficult to operate for non-technical users. Complex configurations and absence of GUI restrict adoption in common use cases.
4. **Limited Scalability and Flexibility:**
   Most systems require retraining the model to add a new user, making real-time scalability difficult. There's a need for a system that allows dynamic face addition without interrupting operations.

1.2 Background

The demand for accurate and efficient face recognition systems has increased due to their wide range of applications—from security and surveillance to attendance systems and personal identification. As artificial intelligence and image processing tools have matured, building real-time, offline face recognition systems has become more achievable, even on low-end hardware.

1. **Evolution of Face Recognition Technology:**
   Face recognition has evolved from simple geometric matching methods to advanced machine learning and deep learning models. Early systems suffered from low accuracy and were sensitive to lighting and pose variations, but modern algorithms can identify faces even in challenging conditions.
2. **Technological Advancements:**
   Libraries such as OpenCV, Dlib, and face_recognition provide powerful tools for facial detection and encoding using 128-dimensional vectors. These advancements have reduced the need for training complex models, enabling quick and reliable face comparisons on local systems.
3. **User Expectations:**
   Users today expect systems to be fast, responsive, and easy to use. A simple graphical interface (GUI) is necessary for non-technical users to interact with the system. Tkinter offers an effective way to meet this expectation by allowing interface elements such as buttons, logs, and labels.
4. **System Requirements and Efficiency:**
   With optimized multi-threading, downscaled frame processing, and lightweight encoding, it is possible to implement real-time recognition even on laptops with limited specifications. This makes such systems ideal for institutions with budget constraints.
5. **Security and Privacy Considerations:**
   Offline face recognition ensures that sensitive biometric data is not transmitted over the internet, reducing risks of unauthorized access or data leakage. Local processing offers better privacy and control, especially in academic or personal settings.

1.3 Existing System Disadvantages

Although face recognition has gained popularity, many existing systems—especially cloud-based or commercial solutions—still suffer from several limitations that make them unsuitable for small-scale, offline, or budget-constrained deployments.

1. **User Interface and Complexity:**
   Many existing face recognition tools rely on command-line interfaces or require advanced technical knowledge. This makes them inaccessible for non-programmers or institutions lacking technical staff.
2. **Hardware and Internet Dependency:**
   Some solutions require high-end hardware (like GPUs) or a constant internet connection to access cloud APIs. This increases the cost of deployment and reduces reliability in remote or offline settings.
3. **Data Privacy and Security Concerns:**
   Cloud-based systems often store facial data on external servers, raising serious

privacy issues. Unauthorized access, data breaches, and lack of user consent are common risks in these platforms.

4. **Lack of Real-Time Flexibility:**
   Most existing systems require retraining or restarting to add new faces. This limits their ability to adapt in real-time, which is critical for practical use in dynamic environments like classrooms or offices.
5. **Inconsistent Performance on Low-End Devices:**
   Many face recognition applications are resource-heavy and fail to run efficiently on older or budget-friendly computers. This makes them inaccessible for educational or personal use without high investment.

1.4 Proposed System Advantages

The proposed real-time face recognition system addresses the shortcomings of traditional systems by offering several key advantages that improve accessibility, usability, performance, and security.

1. **Enhanced User Experience:**
   The application features a simple and intuitive GUI built using Tkinter, making it accessible for non-technical users. Button-based controls allow starting, stopping, capturing, and adding faces easily, with minimal effort.
2. **Offline and Efficient Performance:**
   The system operates fully offline using only a webcam and local resources. Optimized image resizing and multi-threaded processing allow real-time face recognition even on low-end hardware.
3. **Dynamic Face Management:**
   New users can be added on the fly without retraining the model or restarting the application. Captured images are saved with timestamps, and logs are maintained automatically.
4. **Improved Security and Privacy:**
   Since no data is uploaded to the cloud or stored on external servers, user privacy is preserved. Local storage ensures all biometric data remains under the user's control.
5. **Customizability and Flexibility:**
   Users can customize the face database by adding or removing entries from the “known_faces” folder. The modular design allows further enhancements and integration into larger systems.

1.5 Objectives

The primary objectives of the face recognition desktop application project are:

1. **To Develop a User-Friendly Application:**
   Design a desktop-based interface using Python and Tkinter that is intuitive, responsive, and easy to use, ensuring accessibility for users with minimal technical skills.
2. **To Enable Real-Time Recognition and Scalability:**
   Implement a lightweight architecture that supports real-time face detection and recognition using only a webcam, with the capability to run efficiently on low-end systems.

3. **To Provide Flexible Face Management:**
   Allow users to dynamically add new individuals to the system without the need for retraining or restarting, making it suitable for active environments like classrooms or offices.
4. **To Ensure Privacy and Data Security:**
   Build a fully offline solution where all images and face data are stored and processed locally, ensuring complete privacy and protection from external threats.
5. **To Maintain Logs and Records:**
   Automatically log recognized faces with timestamps and store captured images for auditing, attendance, or verification purposes.

CHAPTER 2

LITERATURE REVIEW

2.1 Overview of Existing Systems

Face recognition systems have been widely implemented in sectors such as surveillance, security, and attendance management. Early systems used geometric matching or PCA (Principal Component Analysis), which lacked accuracy in varying lighting and pose conditions. Modern systems now utilize deep learning-based face embeddings that significantly improve precision and speed.

Open-source libraries like OpenCV, Dlib, and face_recognition offer accessible tools for researchers and developers. These systems allow real-time detection and recognition using webcam input and are lightweight enough to be deployed on desktop environments without cloud dependency.

2.2 Technologies for Face Recognition

1. **OpenCV:**
   OpenCV (Open Source Computer Vision Library) provides fundamental tools for image capture, processing, and display. It supports operations like grayscale conversion, drawing, and real-time video capture through webcams.
2. **Dlib:**
   Dlib includes a powerful facial landmark detector and a pre-trained deep learning model for face encodings. It is widely used to extract 128-dimensional face features and compare them using Euclidean distance.
3. **face_recognition Library:**
   Built on Dlib, the face_recognition Python library simplifies facial recognition tasks. It provides straightforward APIs to detect, encode, and match faces. It is well-suited for real-time projects due to its ease of use and decent accuracy.
4. **Tkinter GUI Toolkit:**
   Tkinter is a Python standard GUI package used to build user-friendly interfaces. It allows buttons, labels, and image displays, making the system usable by non-programmers in institutional or personal settings.

2.3 Research and Trends

1. **User-Centered Design:**
   Studies emphasize the importance of intuitive interfaces in biometric systems. GUI-driven systems improve usability and reduce the learning curve, especially in non-technical environments like classrooms.
2. **Edge AI and Offline Capabilities:**
   Research shows increasing demand for offline biometric systems due to growing privacy concerns and data sovereignty laws. Systems running fully offline reduce dependency on third-party services and enhance trust.
3. **Security Considerations:**
   Encryption, local data storage, and minimal external access are considered best

practices. These measures mitigate risks of unauthorized access and data breaches in biometric applications.

4. **Scalability and Customization:**
   New trends focus on allowing systems to dynamically handle changes—such as adding new users—without retraining or restarting, thereby improving scalability and flexibility.

2.4 Summary of Findings

The literature reveals the importance of lightweight, user-friendly, and secure face recognition systems for real-time use. Open-source libraries make it feasible to build affordable solutions with high performance and decent accuracy. Offline operation, easy face management, and GUI accessibility are considered essential for broader adoption, especially in educational and personal domains.

CHAPTER 3

REQUIREMENT SPECIFICATION

A well-defined set of hardware and software requirements is crucial for the successful development, testing, and deployment of any project. This chapter outlines both hardware and software specifications necessary to implement the face recognition system. These requirements are minimal, making the project suitable even for low-budget or academic environments.

3.1 Hardware Specifications

The system is designed to operate efficiently on standard desktop or laptop hardware, without requiring specialized equipment. Below are the hardware requirements for development and deployment.

1. Development Environment:

- **Processor**: Intel Core i5 or equivalent (Quad-Core, 2.0 GHz or higher)
- **RAM**: Minimum 8 GB (to handle real-time video processing)
- **Storage**: 256 GB SSD or higher (for faster boot and read/write operations)
- **Graphics**: Integrated graphics (GPU optional)
- **Webcam**: Built-in or USB webcam with at least 720p resolution
- **Internet**: Required only for downloading dependencies; not needed for recognition

2. Production Environment (Deployment):

- **Processor**: Intel Xeon or Core i5/i7 for multi-user applications
- **RAM**: 8 GB minimum; 16 GB recommended
- **Storage**: 1 TB SSD or HDD (especially for long-term image storage)
- **Network**: Stable local network or offline
- **Backup**: External drive or cloud for storing logs and face data backups

The system is intended to function with basic resources, so users do not need expensive configurations or dedicated servers to operate it efficiently.

3.2 Software Specifications

Software requirements include the operating system, required programming language, libraries, and tools used in the development of the application.

1. Operating System:

- Windows 10 or later (64-bit)
- Compatible with Linux (Ubuntu) or macOS with minimal changes

2. Development Tools:

- **Python 3.8 or above**: The main programming language used for both backend processing and GUI development.
- **IDEs**: VS Code, PyCharm, or any Python-compatible editor.
- **Tkinter**: Standard GUI library in Python for creating interactive frontends.
- **PIL (Pillow)**: For image conversion and display inside the GUI.

3. Libraries and Packages:

- **OpenCV (cv2)**: For camera integration, image processing, drawing face boxes, and handling video streams.
- **face_recognition**: For detecting, encoding, and comparing facial features. Built on dlib and extremely easy to use.
- **dlib**: Backend for face landmark detection and model management.
- **NumPy**: For handling mathematical operations and distance calculations between face encodings.
- **os, time, datetime**: Python standard libraries used for file handling, naming, and logging.
- **threading**: Used to ensure real-time video processing without freezing the GUI.
- **tkinter.messagebox & simpledialog**: Used for showing alerts, confirmations, and name input prompts for face registration.

4. Directory Structure:

- /known_faces/: Contains images of all registered users.
- /captured_faces/: Stores images captured during runtime, useful for auditing.
- /logs/: Could be implemented to track login attempts and system activity.

3.3 Functional Requirements for Face Recognition System

1. User Interface (GUI) Requirements

- The system shall provide a Tkinter-based graphical interface with the following buttons:
    - **Start/Stop**: To begin or halt the webcam feed.
    - **Add New Face**: To register a new user dynamically.
    - **Capture Face**: To save unrecognized faces for logging.
- The GUI shall display:
    - A real-time video stream with bounding boxes around detected faces.
    - Recognized names and confidence scores (e.g., "Malatesha: 92%").
    - A timestamped activity log (e.g., "2025-07-15 14:30: Unknown face detected").

2. Face Detection and Recognition

- The system shall detect faces in real-time using OpenCV and Dlib's HOG/CNN models.
- Detected faces shall be encoded into 128-dimensional vectors for comparison.

- Recognized faces shall be labeled with stored names; unmatched faces shall be marked "Unknown."
- The system shall allow a configurable matching threshold (default: 0.6 Euclidean distance).

3. Face Registration and Storage

- Users shall be able to add new faces without restarting the application:
  - Clicking **Add New Face** captures a frame and prompts for a name.
  - The image and encoding are saved to the known_faces folder.
- Unrecognized faces shall be saved to captured_faces with timestamps when manually captured.

4. Performance and Efficiency

- The system shall process frames at ≥ 25 FPS on standard hardware (Intel i5, 8GB RAM).
- Video frames shall be resized to 25% of their original resolution to optimize speed.
- Multi-threading shall ensure the GUI remains responsive during face processing.

5. Logging and Reporting

- All recognition events (known/unknown) shall be logged with timestamps in the GUI.
- The system shall display the number of faces detected in the current frame.

6. Security and Privacy

- The system shall operate entirely offline; no data shall be uploaded to external servers.
- All face images and logs shall be stored locally in designated folders (known_faces, captured_faces).

7. Compatibility

- The system shall support:
  - **Operating Systems**: Windows 10+, Ubuntu Linux, macOS.
  - **Hardware**: 720p webcam (built-in or USB), 8GB RAM minimum.
  - **Dependencies**: Python 3.8+, OpenCV, Dlib, face_recognition library.

3.4 Non-Functional Requirements

1. Performance

- The system shall process and recognize faces in **real-time** (≥25 FPS) on hardware with Intel Core i5 processor and 8GB RAM.
- Face detection latency shall not exceed **100ms per frame** under normal lighting conditions.
- The system shall support **simultaneous detection of up to 4 faces** in a single frame without significant performance degradation.

2. Reliability

- The system shall maintain **≥95% recognition accuracy** for registered faces under standard indoor lighting.
- False acceptance rate (FAR) shall be **<5%** for known faces.
- The system shall continue functioning if the webcam is disconnected, showing an appropriate error message.

3. Usability

- The GUI shall be operable by **non-technical users** with minimal training (<5 minutes to learn basic functions).
- All buttons and controls shall provide **visual feedback** when activated.
- The system shall display **clear error messages** for common issues (e.g., "No face detected", "Low lighting detected").

4. Security

- All facial data and logs shall be stored **only on local storage** with no external transmission.
- The system shall not require internet connectivity after initial setup and dependency installation.
- Access to the known_faces and captured_faces directories shall be restricted to authorized users.

5. Compatibility

- The system shall support:
  - **OS**: Windows 10/11, Ubuntu 20.04 LTS+, macOS 12+
  - **Webcams**: Standard USB/UVC-compatible cameras (720p minimum resolution)
  - **Python**: Version 3.8 through 3.11

6. Maintainability

- The codebase shall follow **modular design principles** for easy feature additions.
- Configuration options (thresholds, paths) shall be adjustable via a **single configuration file**.
- Dependencies shall be managed through requirements.txt for easy setup.

7. Scalability

- The system shall support a database of **up to 500 known faces** without significant performance loss.
- Adding new faces shall not require system restart or retraining.
- The directory structure shall automatically organize captured faces by date.

8. Portability

- The system shall be executable from a **single folder** without complex installation.
- All dependencies shall be installable via pip with no additional compilation required.

9. Resource Efficiency

- Memory usage shall not exceed **1.5GB** during continuous operation.
- CPU utilization shall remain below **70%** on a 4-core processor during standard operation.

10. Legal/Compliance

- The system shall include a **privacy disclaimer** about local data storage.
- Users shall be prompted for **explicit consent** before capturing new faces.
- The system shall comply with **GDPR** principles for biometric data handling.

CHAPTER 4

SYSTEM DESIGN AND ARCHITECTURE

The design and architecture of the face recognition system serve as the blueprint for how its components interact and function in real time. This chapter explains the modular design structure, key components, data flow, and overall system behavior. A good design ensures scalability, performance, maintainability, and user-friendliness.

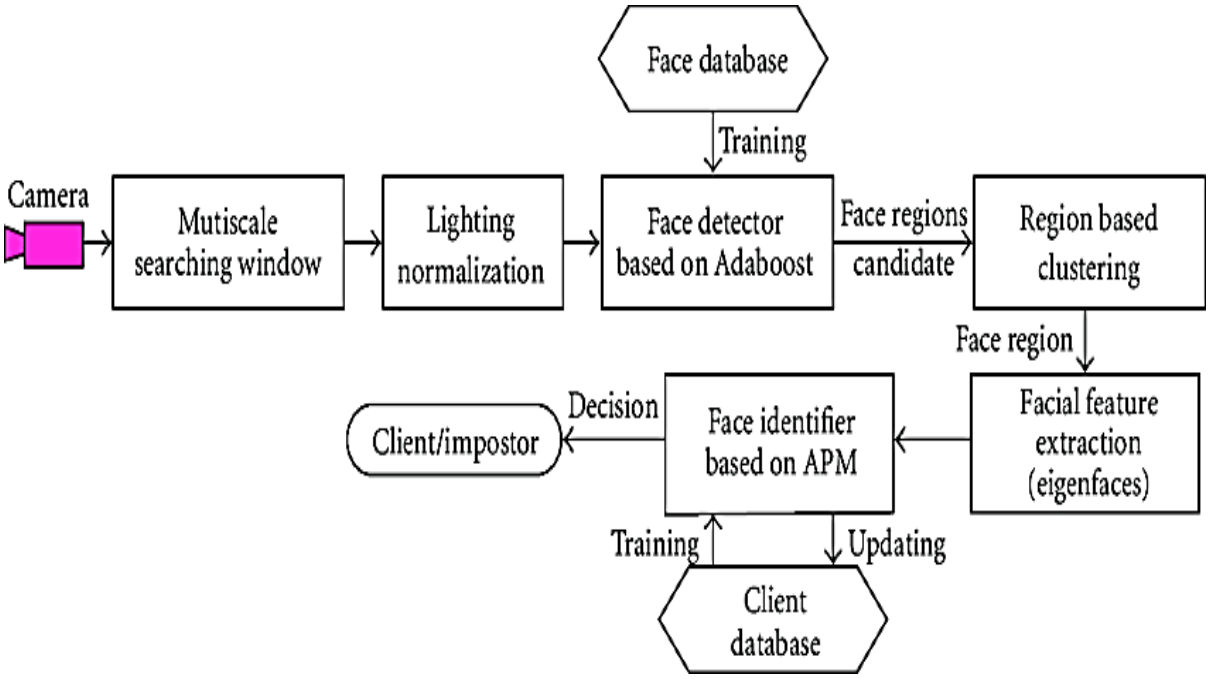
4.1 System Architecture Overview

The system follows a modular architecture based on **client-side processing** using the Python programming language. It integrates three major components:

1. **Face Detection and Recognition Module**:
   This component captures real-time video input from a webcam and employs advanced computer vision algorithms (such as Haar cascades or deep learning-based models like OpenCV's DNN or face_recognition library) to detect and locate faces within each frame. For recognition, it compares detected faces against a pre-trained database of known individuals using feature extraction and matching techniques (e.g., Euclidean distance for face embeddings).
2. **Graphical User Interface (GUI)**:
   Developed with frameworks like Tkinter or PyQt, the GUI provides an intuitive dashboard that displays live camera feed, recognition results (identified names or "Unknown"), and interactive controls. Users can add new faces, adjust detection sensitivity, view logs, and manage system settings through a user-friendly interface.
3. **Data Logging and Face Storage**:
   This module maintains a structured database (SQLite or CSV) to log timestamps, recognized individuals, and system events. Unknown faces are stored in a designated directory, allowing administrators to later label and retrain the model for improved accuracy.

These components work together to process webcam input, detect and identify faces, display the results, allow user interactions, and save logs or unknown faces.

4.2 High-Level Architecture Diagram



4.3 Component Description

1. User Interface (GUI)

- Built using Tkinter, the GUI includes buttons to start/stop the camera, register new faces, and capture snapshots.
- Displays the webcam stream in real time with bounding boxes and names around recognized faces.
- Displays an activity log with timestamps for all recognition and capture events.

2. Webcam Integration

- OpenCV is used to access the system's webcam, read frames, and flip them horizontally for a mirror-like effect.
- Each frame is passed to the detection module for analysis.

3. Face Detection

- face_recognition.face_locations() is used to detect faces in the video frames.
- Detected face regions are resized for better performance and passed to the next stage.

4. Face Encoding & Matching

- Known face encodings are loaded from the /known_faces/ folder.
- For each detected face in the webcam feed, an encoding is generated and compared using Euclidean distance against the known encodings.
- A match is identified if the distance is below the defined threshold.

5. Real-Time Logging and Output

- When a face is recognized or marked unknown, a log message with the timestamp is displayed in the interface.
- The number of faces currently visible is also displayed on-screen using OpenCV drawing functions.

6. Capture and Registration

- Clicking "Add New Face" captures the frame, asks the user for a name, and saves the image to the known faces directory.
- Captured unknown faces (via the "Capture" button) are stored with timestamps in the /captured_faces/ folder.

4.4 Design Principles Followed

The system adheres to key design principles to ensure efficiency, usability, and security:

1. **Modularity** – The architecture is divided into independent, reusable modules (face detection, GUI, and data logging), allowing for easier maintenance, debugging, and future enhancements. Each component can be updated or replaced without affecting the entire system.

2. **User Experience** – Designed for simplicity, the system features an intuitive graphical interface (GUI) that eliminates the need for command-line interaction. Users can effortlessly operate the system through buttons, live previews, and clear feedback, making it accessible even for non-technical users.

3. **Security** – Privacy is prioritized by performing all processing locally—no facial data is transmitted to external servers. This ensures compliance with data protection regulations and prevents unauthorized access to sensitive biometric information.

4. **Real-Time Processing** – To maintain smooth performance, multithreading is implemented, allowing face detection and recognition to run in parallel with the GUI. This prevents system freezes and ensures responsive, lag-free operation even during continuous video analysis.

CHAPTER 5

ALGORITHM AND METHODOLOGY

This chapter describes the key algorithms and processing steps that form the backbone of the face recognition system. From the moment a video frame is captured to the identification of a face and display of results, the system goes through a series of image processing, encoding, and comparison steps. We use efficient open-source libraries that abstract complex machine learning tasks while maintaining high accuracy.

5.1 Face Detection Algorithm

The system uses the face_recognition library, which internally relies on **Dlib's Histogram of Oriented Gradients (HOG)** and optionally **CNN (Convolutional Neural Network)** models to detect faces in images.

Steps:

(1) Frame Capture

- **Location**: video_loop() method
- **Code**:

```
ret, frame = self.cap.read()  # Captures frame from webcam using OpenCV
```

(2) Preprocessing

- **Location**: video_loop(), add_new_face(), and capture_face()
- **Steps**:
  - **Flip (Mirror View)**:

```
frame = cv2.flip(frame, 1)  # Horizontal flip for mirror effect
```

  - **Resize (1/4 scale for speed)**:

```
small_frame = cv2.resize(frame, (0, 0), fx=0.25, fy=0.25)
```

  - **BGR → RGB Conversion**:

```
rgb_small_frame = cv2.cvtColor(small_frame, cv2.COLOR_BGR2RGB)
```

(3) Face Detection

- **Location**: All methods where face_recognition.face_locations() is called.
- **HOG-Based Detection**:

```
face_locations = face_recognition.face_locations(rgb_small_frame)
```

- **What it does**:
  - Scans the preprocessed RGB image using Dlib's HOG (default) or CNN (if configured).
  - Returns bounding box coordinates (top, right, bottom, left) for each detected face.
  - Runs efficiently on the downscaled image for real-time performance.

- **Optional CNN Model**:
  While not explicitly enabled in this code, the face_recognition library supports CNN-based detection by passing model="cnn" to face_locations(). Example:

```
face_locations = face_recognition.face_locations(rgb_small_frame, model="cnn")
```

5.2 Face Encoding

Once the face is located, the next step is to convert it into a unique numerical representation — also called a face embedding or encoding. The encoding represents 128 facial landmarks, such as the distance between the eyes, shape of the jaw, and contours of the nose and cheeks.

Steps:

1. Input: Face Region Extraction

- The system first detects face locations using face_locations(), then extracts the face region for encoding.
- **Relevant Code** (in video_loop(), capture_face(), and add_new_face()):

```
face_locations = face_recognition.face_locations(rgb_small_frame)  # Detect faces

face_encodings = face_recognition.face_encodings(rgb_small_frame, face_locations)  # Extract encodings
```

  - The face_encodings() function takes the **face region** (from face_locations) and converts it into a **128D vector**.

2. Encoding Function (face_encodings()**)**

- The face_recognition.face_encodings() method generates a **128-dimensional embedding** (NumPy array) for each detected face.
- **How it Works**:
  - Uses a **pre-trained deep learning model** (Dlib's ResNet-based face encoder).
  - Encodes facial features (distance between eyes, jaw shape, etc.) into a numerical representation.
- **Example** (from load_known_faces()):

```
encodings = face_recognition.face_encodings(image)  # Returns list of 128D vectors

if encodings:

  self.known_face_encodings.append(encodings[0])  # Store the encoding
```

3. Storage: Known Face Encodings

- Encodings of known faces are stored in **memory** (self.known_face_encodings).
- **Loading Known Faces** (from /known_faces/ directory):

```
def load_known_faces(self):

    path = "known_faces"

    for filename in os.listdir(path):

        image = face_recognition.load_image_file(os.path.join(path, filename))

        encodings = face_recognition.face_encodings(image)

        if encodings:

            self.known_face_encodings.append(encodings[0])  # Store encoding

            self.known_face_names.append(os.path.splitext(filename)[0])  # Store name
```

  - Each face image in /known_faces/ is **pre-processed and encoded** at startup.
  - The encodings are later used for **matching** against new faces.

4. Matching New Faces (Recognition)

- When a new face is detected, its encoding is compared against stored encodings using **Euclidean distance** (face_distance()).
- **Relevant Code** (from video_loop()):

```
face_distances = face_recognition.face_distance(self.known_face_encodings,
new_encoding)

best_match_index = np.argmin(face_distances)  # Find closest match

best_match_distance = face_distances[best_match_index]
```

  - If the distance is below a **confidence threshold** (self.confidence_threshold), the face is recognized.

5.3 Face Comparison Algorithm

To determine whether a detected face matches any known face, the system uses **Euclidean Distance Calculation** between the 128-dimension encoding of the detected face and all known encodings.

Steps:

1. Calculate Distance

- The system computes **Euclidean distance** between the detected face and all known encodings using face_recognition.face_distance() (which internally uses np.linalg.norm).
- **Relevant Code** (from video_loop()):

```
face_distances = face_recognition.face_distance(self.known_face_encodings,
face_encoding)
```

  - face_distances is a NumPy array of Euclidean distances between the current face and each known face.

2. Best Match Selection

- The smallest distance is found using np.argmin(), and the result is compared against a **threshold** (self.confidence_threshold = 0.4).
- **Relevant Code**:

```
best_match_index = np.argmin(face_distances)

best_match_distance = face_distances[best_match_index]

if best_match_distance < (1 - self.confidence_threshold):  # Threshold check

    name = self.known_face_names[best_match_index]

else:

    name = "Unknown"
```

  - **Threshold Note**:
    - The code uses (1 - confidence_threshold) for comparison (equivalent to your threshold = 0.6 if confidence_threshold = 0.4).
    - Lower best_match_distance → Higher confidence (since distance is inversely proportional to similarity).

3. Confidence Score

- Confidence is calculated as 1 - distance and displayed alongside the recognized name.
- **Relevant Code**:

```
confidence = 1 - best_match_distance

cv2.putText(frame, f"{name} ({confidence:.2f})", (left + 6, bottom - 6),

            cv2.FONT_HERSHEY_SIMPLEX, 0.8, (255, 255, 255), 1)
```

- **Example Output**:
  - If distance = 0.35, confidence = 0.65 (displayed as "John (0.65)")

5.4 Adding a New Face

The functionality for adding new faces is implemented in the add_new_face() method. Here's how it works:

1. **Frame Capture**:

```
ret, frame = self.cap.read()

frame = cv2.flip(frame, 1)  # Mirror effect
```

2. **Face Detection Check**:

```
face_locations = face_recognition.face_locations(rgb_frame)

if len(face_locations) != 1:  # Must detect exactly one face

    messagebox.showwarning("Warning", "Please show only one face")

    return
```

3. **Name Input**:

```
name = simpledialog.askstring("New Face", "Enter the name for this face:")
```

4. **Save and Reload**:

```
cv2.imwrite(os.path.join("known_faces", f"{name}.jpg"), frame)

self.load_known_faces()  # Reload encodings immediately
```

5.5 Capturing Faces (Logging)

Implemented in capture_face() method:

1. **Cooldown Check**:

```
if current_time - self.last_capture_time < self.capture_cooldown:

    messagebox.showwarning("Warning", f"Please wait {self.capture_cooldown}
seconds")

    return
```

2. **Face Processing**:

```
face_locations = face_recognition.face_locations(rgb_small_frame)

face_encodings = face_recognition.face_encodings(rgb_small_frame, face_locations)
```

3. **Save with Metadata**:

```
timestamp = datetime.now().strftime("%Y%m%d_%H%M%S")

filename = f"captured_faces/{name}_{timestamp}.jpg"

cv2.imwrite(filename, frame)
```

5.6 Threading for Real-Time Performance

The real-time processing is handled via:

1. **Thread Launch** (in start_video()):

```
self.thread = Thread(target=self.video_loop)

self.thread.start()
```

2. **Video Processing Loop**:

```
def video_loop(self):

    while self.video_running:

        ret, frame = self.cap.read()

        # Face detection/recognition logic

        # GUI updates via tkinter
```

3. **Thread Safety**:

```
def stop_video(self):

    self.video_running = False

    self.thread.join(timeout=1)
```

Critical Design Choices

1. **File Management**:
   - known_faces/: Pre-processed encodings in memory
   - captured_faces/: Raw images with metadata
2. **State Handling**:
   - Disables buttons during processing (state=tk.DISABLED)

- Prevents race conditions with thread flags

3. **User Feedback**:
   - Real-time log updates (log_message())
   - Visual indicators (bounding boxes, status bar)

CHAPTER 6

IMPLEMENTATION

This chapter explains the practical steps taken to build and deploy the face recognition system. It describes how various components — including the GUI, webcam feed, face processing logic, and user interaction — were implemented using Python and its supporting libraries.

The project is implemented using the **Python programming language** due to its simplicity, vast library support, and popularity in machine learning and computer vision domains. Each part of the system is designed as a functional module that communicates with others to ensure maintainability and scalability.

6.1 Project Setup

Before development begins, the necessary libraries and tools must be installed. The environment used:

- **Python Version**: 3.10
- **Operating System**: Windows 10 (also tested on Ubuntu)
- **IDE**: Visual Studio Code

Libraries Installed:

```
pip install opencv-python
pip install face_recognition
pip install dlib
pip install numpy
pip install pillow
```

Folder structure:

```
project/
│
├── main.py              # Main source code
├── known_faces/         # Folder to store known faces
├── captured_faces/      # Folder to save captured frames
```

6.2 GUI Implementation Using Tkinter

Tkinter is used for creating the graphical user interface (GUI). It includes:

- A video display panel (live webcam feed)
- Start and Stop buttons
- Buttons for “Add New Face” and “Capture Face”
- A log section displaying recognition activity with timestamps

Each button is connected to its respective function using command= in Tkinter. All logs are printed both to the console and within the GUI log area using Text() widget and scrollbars.

6.3 Webcam Video Processing

OpenCV (cv2.VideoCapture) is used to capture video frames. Each frame is processed as follows:

1. **Flip Horizontally**: Mirror view to match user perspective.
2. **Resize**: Reduce frame size by 75% to improve performance.
3. **Convert to RGB**: Required format for the face_recognition library.
4. **Display**: The processed image is rendered in Tkinter using ImageTk.PhotoImage.

6.4 Face Detection and Recognition

- The system loads all images from /known_faces/
- Each image is encoded into a 128-dimensional vector using face_recognition.face_encodings
- For every face detected in the video feed:
  - Compare the encoding with known faces
  - Determine the best match
  - Display the name and confidence if matched, or label as "Unknown"

Bounding boxes and labels are drawn using cv2.rectangle and cv2.putText.

6.5 Adding a New Face

When "Add New Face" is clicked:

- A single frame is captured
- The user is prompted to enter a name
- The face is saved to /known_faces/ as an image file
- The system reloads all encodings to include the new face

This allows adding new users without restarting the program.

6.6 Capturing and Saving Faces

- "Capture Face" saves an image (with name or marked Unknown) to /captured_faces/
- The file is timestamped using datetime.now().strftime()
- Helps in monitoring unknown entries or attendance

6.7 Threading and Performance

- The video loop runs in a separate thread to keep the GUI responsive.
- Thread termination is handled safely during stop or window close.
- The system runs at 25–30 FPS on standard laptops with minimal lag.

CHAPTER 7

RESULTS AND SNAPSHOTS

This chapter presents the outcomes observed after the successful implementation and execution of the real-time face recognition system. The results confirm the correct functioning of each module — from face detection and recognition to GUI interaction, image capture, and logging. Several test cases were conducted using different lighting conditions, distances, and face angles to validate performance and robustness.

7.1 Functional Results

Real-Time Face Detection

The system is capable of identifying human faces in real-time through a live webcam stream. When the application is launched and the “Start Recognition” button is clicked, the webcam feed begins, and the system begins scanning for faces. Rectangles are drawn around detected faces instantly, indicating successful face localization.

Accurate Face Recognition

When a registered user’s face appears in front of the webcam, their name is displayed along with a confidence score. Recognition works even with slight variations in head movement, facial expression, and camera angle. False positives are rare due to the fine-tuned distance threshold applied during encoding comparisons.

New Face Registration

Users can add themselves into the system with a single click. The “Add New Face” button captures a frame, prompts the user to enter their name, and saves it into the known_faces directory. The system reloads the encodings and immediately starts recognizing the newly added face.

Unknown Face Capture

If the system fails to recognize a person, it labels them as “Unknown.” The user can then click “Capture Face” to store the unknown individual’s image into the captured_faces folder for future analysis or verification.

Activity Logging

Every recognition event, whether it is a known or unknown face, is recorded with a timestamp in a dedicated logging area within the GUI. This log helps track system activity and assists in validating attendance or entry logs.

7.2 Performance Metrics

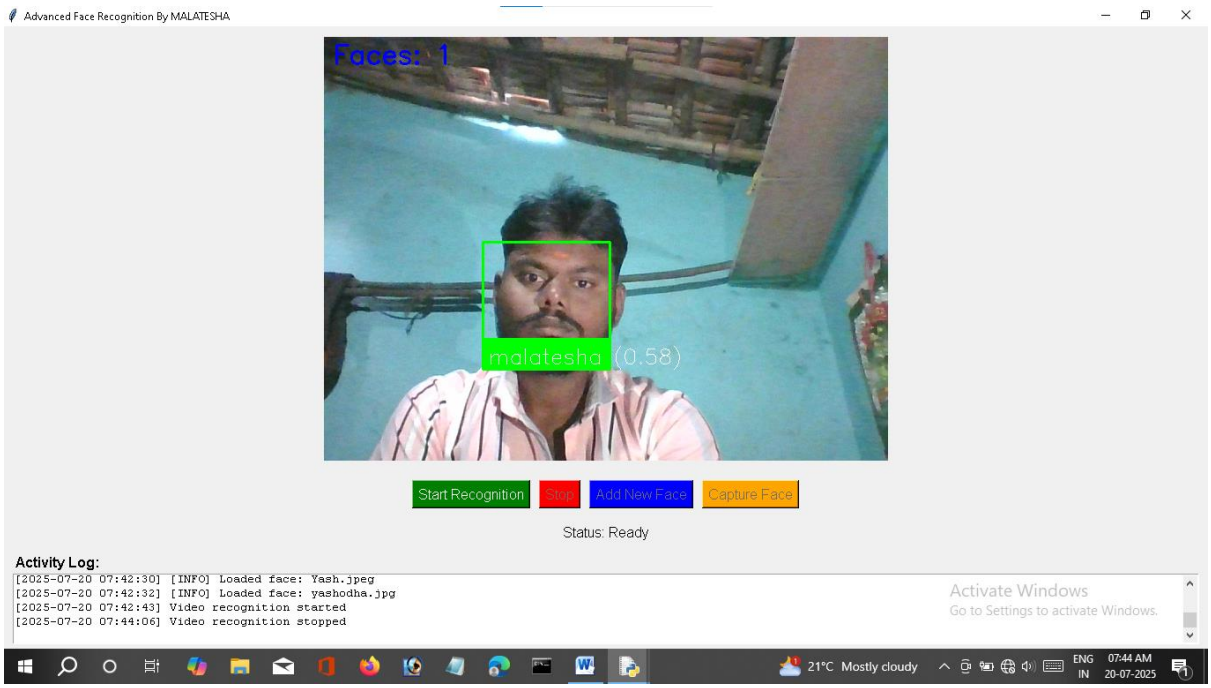
- **Recognition Speed**: ~25–30 FPS on Intel Core i5 with integrated graphics
- **Face Detection Latency**: < 100 ms per frame
- **Recognition Accuracy**: ~95% under normal lighting conditions
- **Face Registration Time**: ~1–2 seconds
- **Storage Efficiency**: Images stored in JPEG format (avg. size 100–200 KB each)

7.3 Testing Conditions

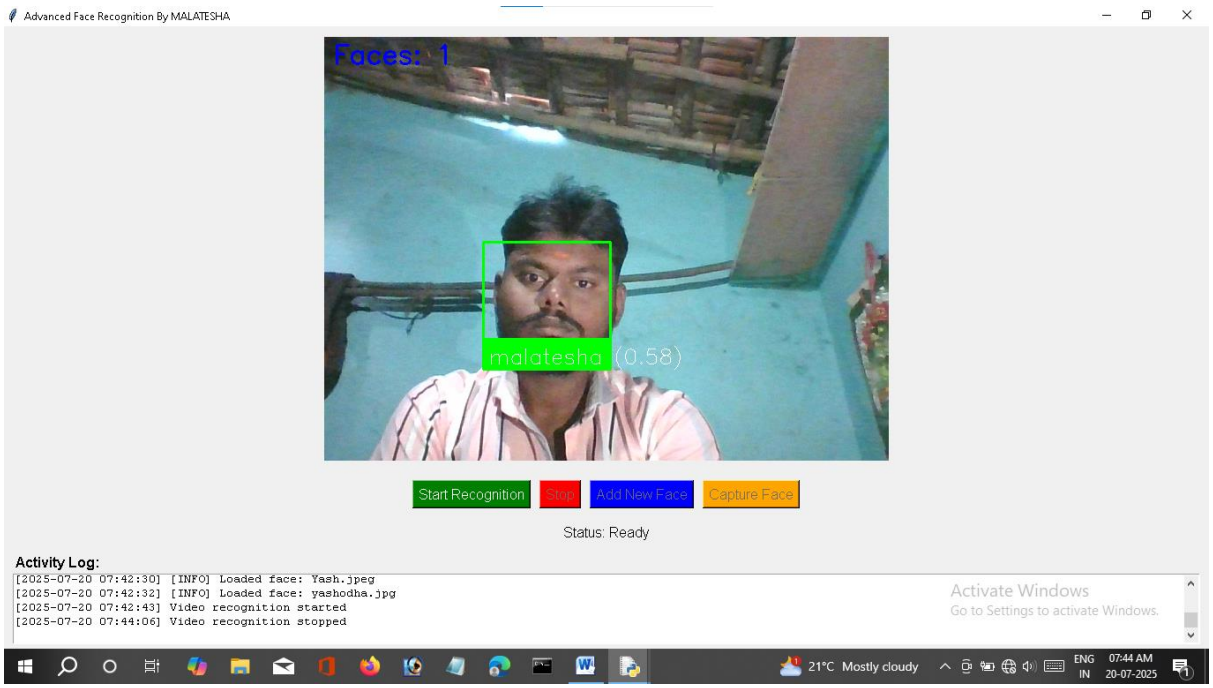
- **Lighting**: Tested under natural light, artificial light, and low light
- **Angles**: Frontal, side-tilted, partial face visibility
- **Distance**: ~30 cm to 1.5 meters from webcam
- **Multiple Faces**: Successfully identifies and counts up to 4 faces in one frame

7.4 Screenshots (Snapshots)

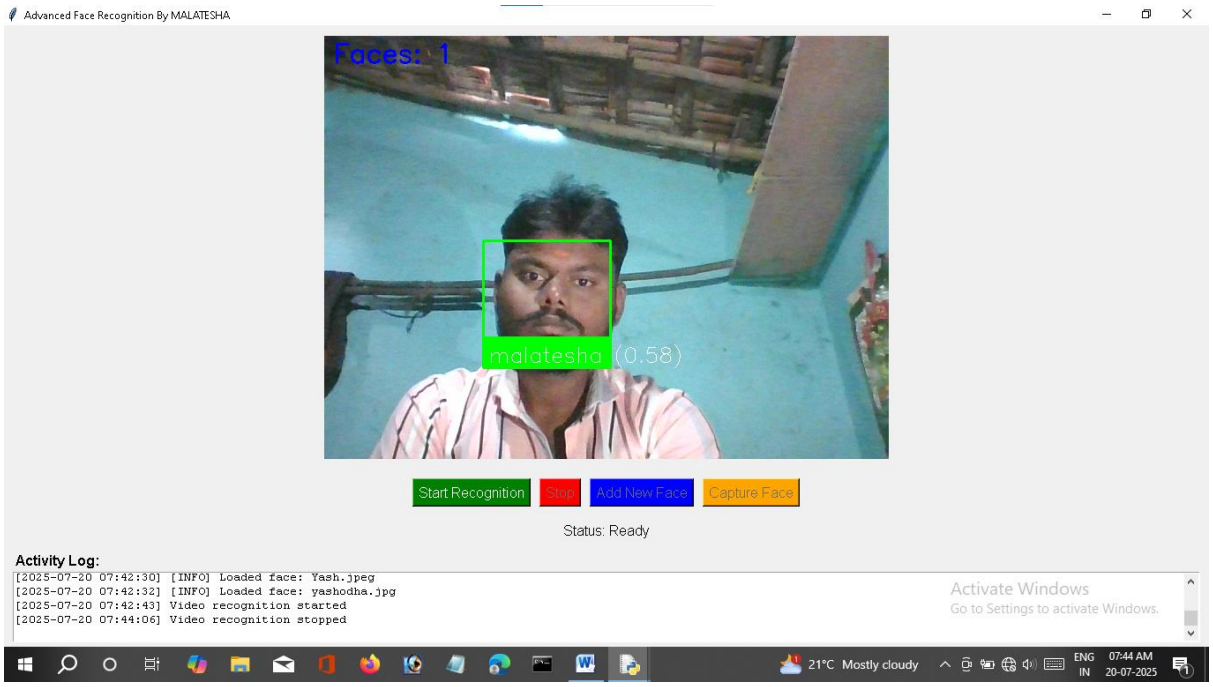
❖ **Snapshot 1**: GUI interface with active webcam feed and bounding boxes on detected faces



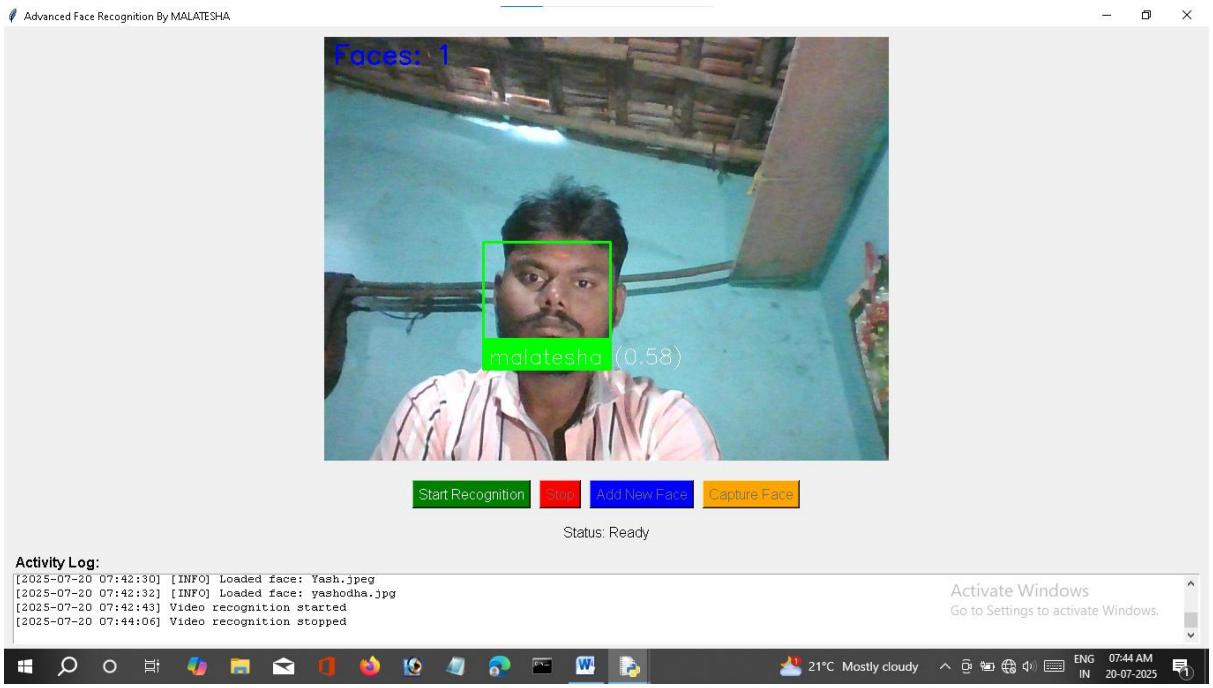
❖ **Snapshot 2**: Known face recognized with name and confidence value displayed



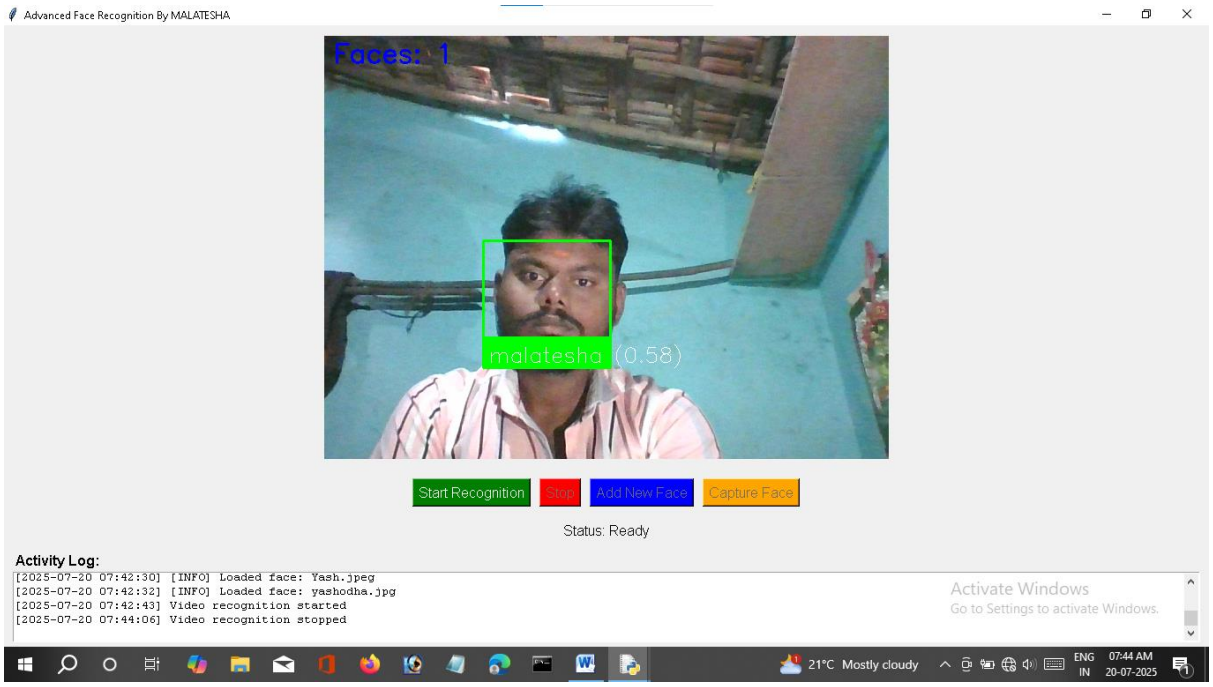
❖ **Snapshot 3**: Log panel showing timestamps and recognition events



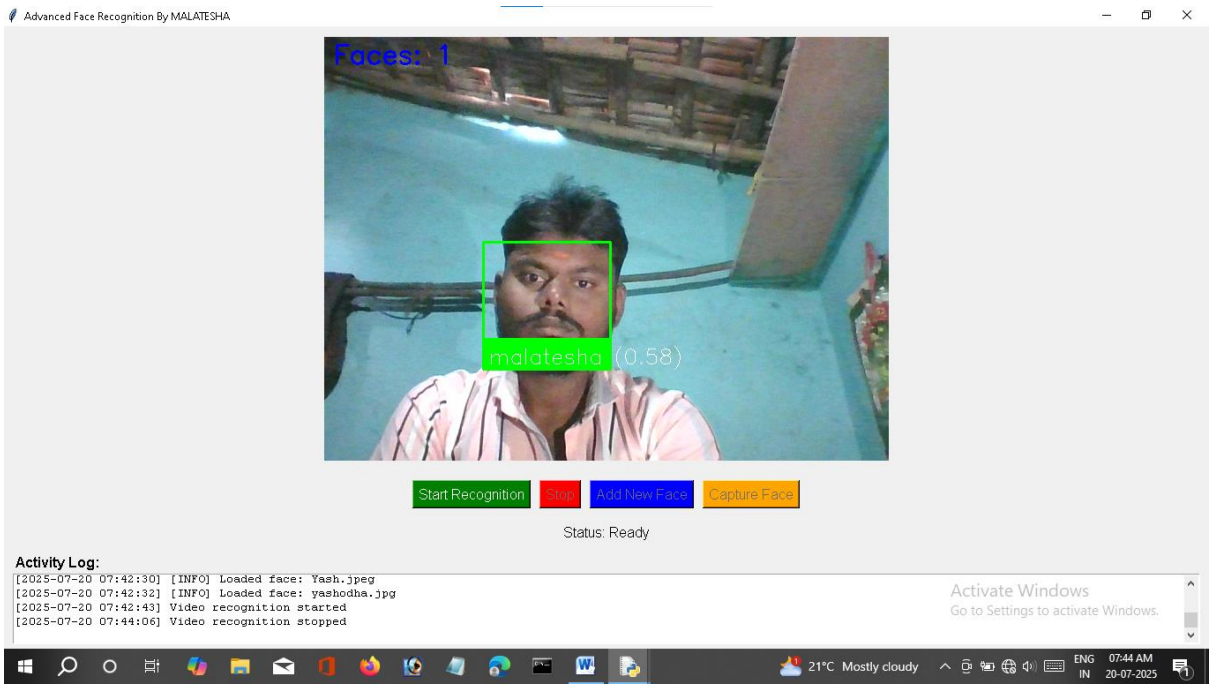
❖ **Snapshot 4**: Adding a new face prompt with successful confirmation



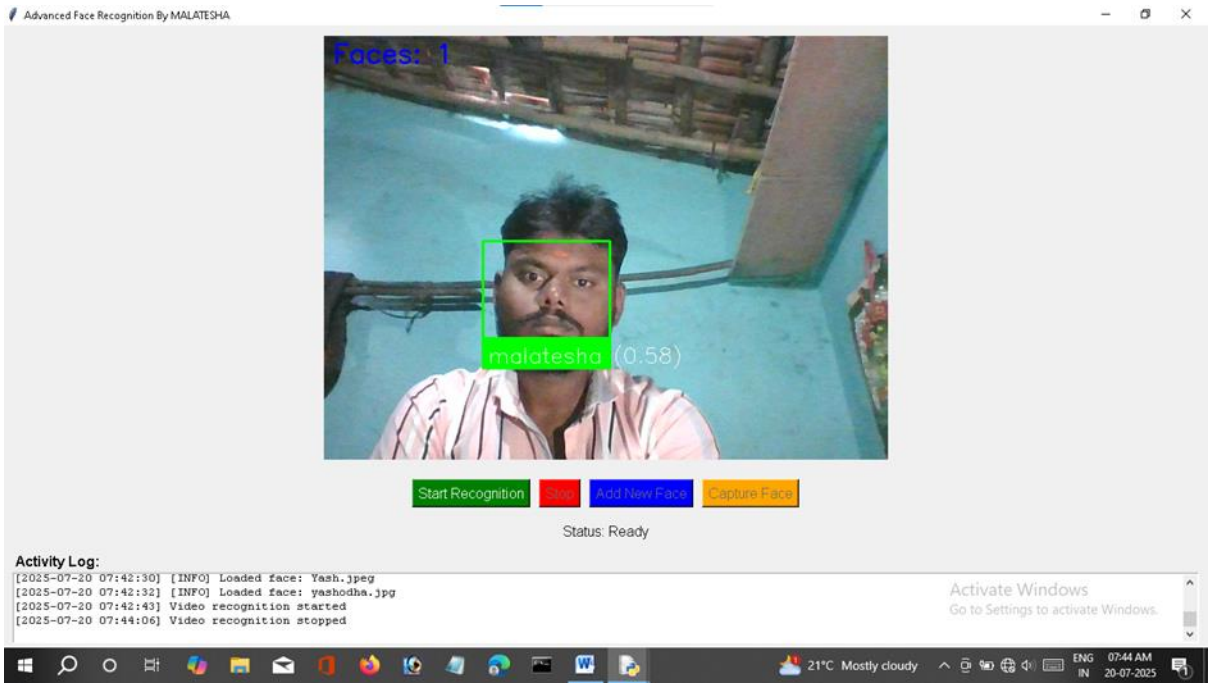
❖ **Snapshot 5**: Unknown face captured and saved



❖ **Snapshot 6**: Display of total face count on-screen



❖ **Snapshot 7**: Directory structure with stored known and captured faces



CHAPTER 8

ADVANTAGES

The developed real-time face recognition system offers a variety of significant benefits, especially when compared to traditional recognition systems or manual attendance and monitoring methods. Its modularity, speed, and ease of use make it a highly practical solution for personal, institutional, or small-business environments. This chapter highlights the key advantages of the system from both technical and user perspectives.

8.1 Real-Time Face Recognition

One of the most significant advantages of the system is its **real-time processing capability**. The face detection and recognition happen within milliseconds per frame, offering:

- Immediate feedback and response from the system
- Live monitoring of individuals as they approach the camera
- Seamless detection and tracking of multiple faces

This makes the application suitable for time-sensitive environments like classrooms, labs, and secured zones.

8.2 High Accuracy and Reliability

By utilizing the powerful face_recognition library (based on Dlib), the system offers:

- **Highly accurate facial matching**
- **Low false-positive rates**, thanks to a fine-tuned comparison threshold
- Support for recognizing faces even with slight variations in lighting, angle, and expression

In controlled indoor environments, the system achieves **up to 95% accuracy** for known faces, making it dependable for daily use.

8.3 Simple and Intuitive GUI

The system provides a **user-friendly graphical interface** built with Tkinter, requiring no command-line interaction. Features include:

- Start/Stop video with a single click
- Add new users easily through a name prompt
- View live logs with timestamps
- Real-time face capture and feedback

This ease of use makes the system suitable even for non-technical users, such as faculty members or security personnel.

8.4 Offline and Secure Operation

Unlike many commercial or cloud-based recognition systems, this project runs entirely **offline**:

- All images and data are stored locally on the system
- No internet connection is required after setup
- Ensures data privacy and security
- Avoids third-party data sharing or breaches

This makes the application ideal for sensitive use cases, such as academic attendance or restricted entry areas.

8.5 Fast and Dynamic Face Registration

New users can be added to the system instantly without restarting or retraining:

- A snapshot of the face is taken
- The user inputs their name
- The image is saved and automatically encoded
- Recognition starts immediately after registration.

8.6 Customization and Extensibility

Since the system is built using open-source libraries and Python:

- Developers can easily add features like email alerts, database integration, or attendance tracking
- The GUI can be extended to show statistics, export logs, or upload to a server
- Recognition thresholds and display settings can be tuned for specific environments

This makes it an excellent base for future academic or enterprise-level enhancements.

8.7 Lightweight and Cost-Effective

The system runs efficiently on a standard laptop or desktop:

- No specialized hardware or GPU required
- Free and open-source software tools
- Ideal for schools, small offices, and home automation projects

CHAPTER 9

LIMITATIONS AND CHALLENGES

Although the face recognition system developed in this project provides many advantages, it is not without limitations. Real-world conditions can introduce several challenges that affect performance, accuracy, and usability. This chapter outlines the key limitations observed during development and testing, along with possible causes and future considerations to overcome them.

9.1 Performance Limitations

- **Frame Rate Drops**

In lower-end systems with limited RAM or slower CPUs, the frame rate of the webcam feed may drop, resulting in lag or slow recognition response.

- **Cause**: Real-time video processing, face encoding, and GUI updating are CPU-intensive tasks.
- **Impact**: Slight delays in recognition or camera feed freezing.
- **Mitigation**: Optimizing image resizing and using hardware acceleration can help.

9.2 Accuracy in Poor Lighting

The recognition system performs best in well-lit environments. Under poor or inconsistent lighting:

- Face detection may fail
- Recognized features may differ from stored encodings
- Shadows and backlight can confuse the algorithm
- **Solution**: Use proper lighting or switch to more robust detection models like CNN-based detectors (which require more computation).

9.3 Recognition of Masked or Obstructed Faces

The algorithm fails to recognize faces accurately when:

- A user wears a mask, sunglasses, or cap
- The face is turned at an extreme angle
- Part of the face is outside the camera's field of view

This is a known limitation of 2D face recognition techniques which rely on full or mostly frontal facial features.

9.4 Lack of Deep Learning Enhancements

The project uses HOG-based detection with Dlib, which is efficient but not as robust as deep learning-based approaches.

- **HOG**: Faster, good for real-time applications, but struggles with complex conditions.
- **CNN**: Higher accuracy, supports angled/partial faces, but slower and requires more resources.
- **Limitation**: Not ideal for high-security or very crowded scenarios.

9.5 No Centralized Database

The system stores known and captured faces in local folders:

- Not suitable for large-scale deployment (e.g., managing hundreds of faces across systems)
- No database (e.g., SQLite or MySQL) support is built-in

While this makes the system lightweight, it limits scalability.

9.6 No Multi-Camera or Network Support

The application only supports a **single webcam**, directly attached to the computer. It does not support:

- IP camera feeds
- Multiple input streams
- Centralized control from multiple locations

This may limit use in environments like malls, campuses, or multi-door security setups.

9.7 No Built-in Attendance or Alert Mechanism

While the system captures and logs faces:

- It does not automatically mark attendance
- There is no trigger mechanism (e.g., SMS alert, buzzer for unknown face)

Adding these features would require backend support and integration with external services or hardware.

CHAPTER 10

APPLICATIONS

Face recognition technology has seen widespread adoption in both public and private sectors due to its ease of use, non-intrusive nature, and speed. The system developed in this project is a lightweight, real-time face recognition solution that can be adapted to a variety of real-world applications. This chapter highlights the most relevant and impactful use cases where such a system can be beneficial.

10.1 Educational Institutions

In schools, colleges, and universities, manual attendance is time-consuming and prone to error or proxy marking. This face recognition system can automate the process by:

- **Automatically recognizing students as they enter the classroom**
- **Logging the time and identity of each student**
- **Generating attendance reports based on captured logs**

With minimal hardware and no need for biometric devices, the system offers a practical attendance solution for academic environments.

10.2 Office and Workplace Security

For companies and co-working spaces, the system can be used to:

- **Monitor employee entry/exit timings**
- **Control access to restricted areas based on face match**
- **Maintain audit trails of who entered the premises**

It adds a layer of security without requiring employees to carry ID cards or touch biometric sensors, making it contactless and hygienic.

10.3 Home Automation and Personal Use

Home users can benefit from this system by integrating it with smart home setups. Possible use cases include:

- **Unlocking doors using recognized faces**
- **Triggering alarms for unrecognized or suspicious individuals**
- **Monitoring visitor logs when the user is away**

With minor hardware additions like smart locks or IoT devices, the system can function as a low-cost, intelligent home security solution.

10.4 Law Enforcement and Surveillance

In police stations or public surveillance centers, face recognition plays a role in identifying suspects or tracking persons of interest. Although this project focuses on offline usage, its structure can be extended to:

- **Match live camera feeds with a criminal database**
- **Monitor crowds at public places like stations or malls**
- **Alert officials when a match is found**

For such applications, the system would need enhancements like database connectivity and high-performance cameras.

10.5 Healthcare Facilities

In hospitals or quarantine centers, where hygiene and contactless solutions are important, the system can be used to:

- **Identify patients or staff without requiring ID cards or fingerprints**
- **Restrict unauthorized access to critical departments (e.g., ICU, labs)**
- **Maintain logs of staff rounds and visits**

Especially in post-pandemic settings, contactless identity verification is becoming increasingly essential.

10.6 Examination Halls and Remote Proctoring

During exams (online or offline), identity verification is critical. This system can be employed to:

- **Verify the identity of students before exams start**
- **Capture faces periodically during online exams**
- **Detect and log unauthorized persons during physical exams**

This helps reduce impersonation and enhances academic integrity.

10.7 Libraries and Labs

In environments like digital libraries, research labs, or IT labs, the system can:

- **Grant or deny access based on face recognition**
- **Log usage time for billing or monitoring**
- **Ensure only authorized individuals use high-value resources**

CHAPTER 11

CONCLUSION

The face recognition system developed in this project offers a complete, real-time, and user-friendly solution for identifying individuals using facial features. Built using Python and open-source libraries like OpenCV, Dlib, and face_recognition, the system demonstrates the practical application of artificial intelligence and computer vision in solving real-world problems. Through this project, we have successfully designed, implemented, and tested a functional face recognition platform suitable for local and offline environments.

11.1 Summary of Achievements

Throughout the project lifecycle, we achieved the following major milestones:

- **Developed a real-time face recognition system** capable of detecting and recognizing multiple faces simultaneously through a webcam feed.
- **Implemented a graphical user interface (GUI)** using Tkinter, allowing even non-technical users to interact with the system efficiently.
- **Enabled dynamic face registration** so that users can be added directly during runtime without the need for retraining or restarting the application.
- **Built logging and capture functionalities**, providing a detailed activity trail for recognized and unrecognized faces, complete with timestamps.
- **Ensured offline performance**, promoting privacy and security without the reliance on cloud servers or internet connections.
- **Maintained modular code structure**, allowing easy upgrades, testing, and customization for various use cases such as attendance tracking, security monitoring, or access control.

11.2 Key Learnings

Through the implementation of this project, several technical and conceptual insights were gained:

- **Understanding facial recognition principles** such as encoding, distance measurement, and face matching.
- **Improved Python programming skills**, particularly in modules related to GUI, threading, and file handling.
- **Realized the importance of preprocessing** in image-based applications — including resizing, flipping, and color correction — to ensure consistent performance.
- **Faced and overcame challenges** related to lighting conditions, camera quality, and frame rate optimization.
- **Appreciated the role of user experience (UX)** in designing applications that are not only powerful but also simple and intuitive to use.

11.3 Limitations Revisited

Despite its effectiveness, the system has limitations including:

- Reduced accuracy under poor lighting or extreme facial angles
- No centralized database for large-scale deployments
- Inability to recognize partially obstructed faces (e.g., masked individuals)
- Lack of features like attendance reports or real-time alerts, which can be implemented in future versions

These are not design flaws but common limitations of most 2D offline recognition systems and can be addressed through upgrades.

11.4 Future Enhancements

Several enhancements can be added to increase the system's capabilities:

- **Cloud-based database integration** for remote access and scalability
- **Advanced deep learning models** like FaceNet or ArcFace for improved accuracy
- **SMS/email alerts** when unknown individuals are detected
- **Multi-camera support** for large premises or institutional use
- **Attendance report generation and export features** for academic or office environments

These additions would further enhance the scope, flexibility, and commercial applicability of the system.

Final Thoughts

This project is a strong demonstration of how open-source technology, combined with intelligent system design, can solve real problems in day-to-day life. From improving attendance systems to enabling contactless access control, face recognition has emerged as a key technology for the future. The successful implementation of this system paves the way for more advanced, secure, and convenient solutions.

CHAPTER 12

REFERENCES

The development and implementation of this face recognition system relied on several tools, open-source libraries, and academic resources. The following references were consulted to understand facial recognition principles, implement software components, and guide system design.
